Abstract

**Objective:** To investigate whether systematic reviews of mediation studies identify limitations in reporting quality and methodological conduct.

**Study Design and Setting:** An overview of systematic reviews. We searched four databases (MEDLINE, PsycINFO, Cochrane Database of Systematic Reviews and PubMed) to identify systematic reviews of studies that used mediation analysis to investigate mechanisms of healthcare interventions or exposures in clinical populations between 2007 and 2017. Two reviewers independently screened titles and abstracts. Summary data on the characteristics, reporting quality and methodological conduct of the studies included in the systematic reviews were extracted independently by two reviewers. The protocol was prospectively registered on PROSPERO (CRD42017059834).

**Results:** 54 systematic reviews were included, representing 11 healthcare fields, 26 health conditions and 2008 mediation studies. 18/54 systematic reviews (33%) explicitly stated that the reporting of primary studies was suboptimal. Of these, 14/18 (78%) reviews noted incomplete reporting of effect sizes and precision estimates from mediation analyses. 29/54 systematic reviews (54%) identified limitations in the methodological conduct of primary studies.

**Conclusion:** The reporting and methodological conduct of studies investigating mechanisms in healthcare seems to be suboptimal. Guidance is needed to improve the quality, completeness and transparency of mediation studies.

**Key words:** Mechanism; mediation analysis; overview; quality of reporting; causal inference
Running title: Reporting and methodological quality of healthcare studies investigating mechanisms

Word count: 193 (abstract: 200max), 2673 (excluding imbedded text around figure titles and legends) (main text: 3000 max), 4 tables, 4 appendix files
Key findings

• Mediation analysis is a popular method for studying the mechanisms by which health interventions or exposures exert their effects.

• This overview shows that over the past decade, there were 54 published systematic reviews including 2008 primary mediation studies, across 11 healthcare fields and 26 health conditions.

• Eighteen of fifty-four (33%) systematic reviews identified limitations in reporting quality and twenty-nine of fifty-four (54%) systematic reviews stated limitations in the methodological conduct of the primary mediation studies.

What this adds to what is known?

• Historically, mediation studies were common in fields such as psychology. This overview has shown that mediation studies are also conducted in health and medical fields across a range of health conditions.

• Systematic reviews of mediation studies have identified suboptimal reporting quality and methodological conduct of primary studies that study the mechanisms of health interventions and exposures.

What is the implication and what should change now?

There is a need to improve the reporting and methodological quality of studies investigating mechanisms. Improving reporting and methodological standards for mediation studies will enhance the ability to evaluate, reproduce and synthesise the findings of mediation studies. It may also minimise reporting bias in systematic reviews of mediation studies.
1. Introduction

Identifying the mechanisms that underpin the effect of healthcare interventions can help refine interventions to improve health outcomes and facilitate the translation of research findings into clinical practice and policy [1–3]. Recently, the US National Institute of Health (NIH) and UK National Institute for Health Research (NIHR) recommended embedding mechanism evaluations into clinical trial programs to explain how interventions work, so that they can be tailored for implementation (NIH Science of Behaviour Change Common Fund Program, and NIHR Efficacy and Mechanisms Evaluation program). The UK Medical Research Council have also endorsed the value of studying mechanisms as part of process evaluations of complex health interventions [3].

The most frequently used quantitative method for evaluating causal mechanisms is mediation analysis [4,5]. Mediation analysis is used to provide insight into how health interventions or exposures exert their effects on outcomes. Mediation analyses are commonly used in epidemiological studies and randomised controlled trials. For example, in a randomised controlled trial of adults with type-2 diabetes mellitus, Rejeski et al. (2012) used mediation analysis to understand how a complex lifestyle programme (intervention) improved mobility (outcome) through its effect on weight loss (mediator) [6]. In an observational cohort study of premature infants, Chawla et al. (2016) investigated how the effect of antenatal steroids (exposure) on neurodevelopmental impairment (outcome) was mediated by reducing rates of severe intracranial haemorrhage (mediator) [7].

There are several analytical approaches to mediation analysis [8]. The fundamental goal is to decompose the ‘total effect’ of an intervention (or exposure) on an outcome into an
'indirect effect' that is channelled through a selected mediator, and a ‘direct effect’ that is not channelled through the selected mediator [4]. The goal of systematic reviews of mediation studies may be to estimate pooled average indirect or direct effects across studies. This may be challenging if primary mediation studies fail to adequately report the methods and results, including indirect and direct effects and their precision estimates.

Although there is guidance on how to conduct mediation analyses [4,5,9,10], there is a lack of guidance on how researchers should report mediation studies. Thus, it is possible that the accuracy and completeness in the reporting of mediation studies is varied in the literature. Inaccurate and incomplete reporting of mediation studies can limit the usability of the evidence, stifle reproducibility, and restrict the inclusion (or exclusion) of reliable information for systematic reviews and meta-analyses [11]. Although reporting practices for mediation studies may vary across healthcare fields and impose problems for evidence use and synthesis, it is unclear if a separate reporting guideline for mediation studies is needed, or whether a reporting guideline would significantly reduce the number of poorly reported studies.

The Guidance for Developers of Health Research Reporting Guidelines (Moher et al., 2010) [12] states that the first step in developing a reporting guideline is to identify the need for a new reporting guideline by evaluating published research [12]. Although the evidence for this need can be obtained in several ways, it is important to consider where inadequate reporting has the greatest impact [13]. Systematic reviews often experience limitations in synthesising and interpreting primary research findings due to inadequate or varied reporting of primary studies [14]. Systematically summarising the limitations identified by Cashin et al. (2018)
systematic reviews presents as a method to assess which common problems have been identified. There is precedent for this approach; Slade et al. (2012) [15] conducted an overview of systematic reviews which identified the need for better and standardised reporting of exercise prescription in the development of the Consensus on Exercise Reporting Template [16].

We conducted an overview of systematic reviews of studies investigating mechanisms in healthcare, published from 2007 to 2017. The overarching aim of this overview was to identify the need for a reporting guideline for mediation studies in healthcare research. The specific aims of this overview were to: 1) identify whether reporting and methodological problems of primary mediation studies are encountered by systematic reviews when synthesising the evidence; and 2) summarise and describe the reporting and methodological limitations highlighted by systematic reviews.

2. Methods

This overview is reported in accordance with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) statement [17]. The protocol for this review was registered on the 22\textsuperscript{nd} March 2017 on the PROSPERO International Prospective Register of Systematic Reviews (CRD42017059834), accessible at https://www.crd.york.ac.uk/prospero/display_record.php?RecordID=59834. Protocol deviations are reported in Appendix A1.

2.1. Eligibility criteria
We included articles that used systematic methods to identify and review primary mediation studies that aimed to investigate the mechanisms of health interventions or exposures. We included all clinical populations and populations of individuals at-risk of developing a health condition. We included systematic reviews published in the 10 year period from March 22, 2007, to March 22, 2017 that synthesised studies on human participants of any age. We excluded non-English publications, articles for which full texts were unavailable, articles for which the primary aim was not to review mechanisms, and articles describing only the design or protocol of a systematic review.

2.2. Search strategy

We searched MEDLINE (OvidSP), PsycINFO (OvidSP), Cochrane Database of Systematic Reviews (OvidSP) and PubMed databases (March 22, 2007, to March 22, 2017). The full search strategy is available in the Appendix A2. We downloaded the search results into EndNote™ and exported them to Microsoft Office Excel. Further, we hand searched the reference lists of included studies for eligible articles. AC and HL independently screened titles and abstracts and selected articles for full text review using the inclusion/exclusion criteria, and then independently reviewed the full texts to determine eligibility. AC and HL resolved disagreements through discussion and reaching consensus.

2.3. Data extraction

Two reviewers (AC, GM or HL) independently extracted data using a data extraction form developed for the study (Appendix Table A3). Disagreements were resolved through discussion. AC, GM and HL were not blinded to the journal or review authors. We extracted information about the systematic reviews, including: the year of publication, healthcare...
field, target population, aim, number of studies included, data synthesis approach, and the types of effects that were pooled in a meta-analysis (if conducted). We also extracted information reported in the systematic reviews about the synthesised primary studies, including: study design, ratio of randomised and non-randomised study designs, and types of mediation analyses conducted. Finally, we extracted information about any limitations identified by the systematic reviews that were associated with the reporting and methodological conduct of the primary studies.

2.4. Data synthesis

Categorical variables were summarised using frequencies and percentages. Continuous variables were summarised using mean and standard deviation or median and interquartile range. Information on reporting quality and methodological conduct of the primary studies that were identified by the systematic reviews were extracted verbatim and grouped into common themes according to meaning and content. Themes were summarised using frequencies and percentages.

3. Results

3.1. Study selection

A total of 2457 records were identified through the database search and hand searching of reference lists (Figure 1). Following duplicate removal and title and abstract screening, 118 systematic reviews remained for full text screening. Sixty-four systematic reviews were excluded for the following reasons: not a clinical or at-risk population (n=22), not a systematic review (n=20), primary aim was not to review mechanisms (n=21), and non-Cashin et al. (2018)
human sample (n=1). Finally, 54 systematic reviews met the inclusion criteria and were included in the overview [18,19,28–37,20,38–47,21,48–57,22,58–67,23,68–71,24–27].

3.2. Description of systematic reviews

Most reviews (n=33/54) were published between 2013 and 2017. The reviews were conducted across 11 healthcare fields and 26 healthcare conditions (Table 1).

Cashin et al. (2018)
The median number of primary mediation studies included in the systematic reviews was 27 (IQR 15-52). In total, the systematic reviews included 1213 non-randomised studies, 725 randomised studies, and 70 studies that were unclassified. The inclusion criteria for study design and the synthesis methods used by systematic reviews are presented in Table 2.

Of the 54 systematic reviews, 15 (28%) performed a meta-analysis of the primary studies. Of these studies, 3/15 (20%) pooled the indirect effect, 2/15 (13%) pooled the direct effect, 12/15 (80%) pooled the total effect, and 3/15 (20%) pooled fragments of the indirect effect (exposure-mediator effect and/or mediator-outcome effect). If data were available, reviews could have conducted an individual participant data meta-analyses (IPDMA). Only one review reported the results of an IPDMA [33].

3.3 Reporting quality

Cashin et al. (2018)
Of the 54 systematic reviews, 18 (33%) provided information about limitations encountered through the reporting quality of the primary studies. The specific reporting limitations are summarised in Table 3. None of the systematic reviews explicitly aimed to assess the reporting quality of the synthesised studies, nor did they identify a specific reporting tool or existing reporting guideline for mediation studies.

3.4 Methodological quality

Of the 54 systematic reviews, 29 (54%) provided information on the methodological quality of the primary studies, directly related to mediation. All 29 studies highlighted at least one methodological limitation specific to mediation analysis (Table 4).

3.5 Risk of bias

Of the 54 systematic reviews, 33 (61%) reviews reported the use of a risk of bias tool; of these reviews, ten used a tool they had specifically adapted for mediation studies, and twenty-three used a general risk of bias tool (eg. Cochrane Collaboration’s risk of bias tool [72], the Jadad criteria [73], Newcastle-Ottawa Scale [74]).

4. DISCUSSION

Our overview included 54 systematic reviews of 2008 primary mediation studies across 11 healthcare fields and 26 different health conditions. Most systematic reviews (n=33) were
published between 2013 and 2017, which suggests a recent increase in the volume of mechanism investigations in healthcare research. Specialist fields such as oncology [48], endocrinology [22], neurology [61] and infection control [62] are also beginning to utilise mediation analyses in randomised controlled trials and observational studies.

4.1 Reporting limitations

One-third of the systematic reviews reported limitations in synthesising primary mediation studies due to inadequate reporting. Most often, these reviews identified that the primary studies reported insufficient detail about the statistical analysis and did not report key effect estimates (e.g. indirect effects) that are critical for the interpretation of mediating effects. This overview did not aim to assess an extensive list of all possible items that should be reported in mediation studies. The findings from our overview are consistent with those of methodologically focussed reviews of mediation studies. For example, Gelfand et al. (2009) found that 52% of a random sample of 50 primary mediation studies did not report all relevant effects in a mediation model [75]; Wood et al. (2008) highlighted that 62-74% studies in organisational research did not report power calculations for mediating effects [76]; Hertzog (2018) and Lapointe-Shaw et al. (2018) identified that 23% and 65% of mediation studies in nursing and healthcare research did not report assumptions required for making valid causal inferences [77,78]; and Mansell et al. (2013) observed that 86% of mediation studies in the back pain literature did not report the measurement properties for both mediator and outcome variables [79]. Recently, Liu et al. (2016) and Lapointe-Shaw et al. (2018) both concluded that the reporting of mediation studies in epidemiology and time-to-event healthcare research was varied and suboptimal, and highlighted the need for formal guidance to improve reporting standards [78,80].

Cashin et al. (2018)
Only a quarter (28%) of reviews identified sufficient information and data to pool mediation effects in a meta-analysis. There could be several reasons for this. There may have been insufficient information reported in the primary mediation studies for systematic reviewers to decide whether it was appropriate to pool effect estimates. Some reviews may have decided not to pool effect estimates because key effect estimates were not reported (or reported inconsistently) across the primary studies that were reviewed. This is supported by our data showing that mediation studies often did not report key effect sizes and their precision estimates. The low number of meta-analyses may also be explained by issues unrelated to poor reporting practices. For instance, reviews may have found insufficient numbers of primary studies that tested consistent mediators across studies. For the small number of reviews that did pool effects, there was substantial heterogeneity in the types of effects that were pooled, with some reviews pooling fragmented components of the indirect effect. This in part may have resulted from poor reporting quality in the primary mediation studies or from heterogeneity between studies, such as different mediators being explored.

Following the Guidance for Developers of Health Research Reporting Guidelines (Moher et al. 2010) [12], the second step in developing a reporting guideline is to search for relevant existing guidance in the area. A search of the Enhancing the QUAlity and Transparency Of health Research (EQUATOR) network database in July 2016 showed that there are no existing guidelines or guidelines under development for mediation studies [81,82]. Our findings and those of others [78,80] suggest that existing guidelines such as the CONSORT for randomised controlled trials or STROBE for observational studies do not cover the
unique aspects of study design, analysis, and results that should be reported in a mediation study [78,80]. Requirements to justify the development of a reporting guideline have not been precisely defined [83]. However, our overview has shown that inadequate reporting of primary mediation studies can stifle systematic reviews; and the accumulating evidence of inadequate reporting of mediation studies [75–80], suggests that a guideline may help improve reporting standards.

4.2 Methodological limitations of mediation studies

We found that over half of the systematic reviews provided information about limitations in the methodological conduct of studies investigating mechanisms. A quarter of the reviews suggested that primary mediation studies used inappropriate study designs to infer causality (31%) and used inappropriate statistical methods to estimate mediating effects (28%). It was unclear how the review authors defined the use of appropriate methods and statistical analysis techniques. Given that several new methods for mediation analysis have been introduced during the past decade [4], the implicit definition of appropriate or inappropriate methods is likely to vary between reviews. Therefore, we cannot be sure about the extent of methodological issues in mediation studies. However, our findings are consistent with previous work. For example, Fairchild and McQuillin (2010) [84] concluded that studies were often underpowered, and cross-sectional study designs were used to examine causal mechanisms; Wood et al. (2008) [76] found strong publication bias for significant effects; and Cerin and MacKinnon (2009) [85] noted the use of incompatible (linear) analytic methods for binary outcomes, and a lack of adjustment for exposure-mediator interaction effects. Based on these observations, it seems that a risk of bias tool could help improve the quality of mediation analyses in applied health research.

Cashin et al. (2018)
4.3 Limitations

As our overview leveraged published systematic reviews, our indirect appraisal of primary studies may have underestimated the methodological and reporting problems of mediation studies in healthcare. For example, in 61% (n=33/54) of the included systematic reviews, it was not possible to determine which mediation analysis method was used by the primary studies. This may be due to inadequate reporting of the primary study, or because systematic reviews did not extract information on analytical methods. None of the included systematic reviews explicitly aimed to review limitations in the reporting or methodological conduct of primary mediation studies. Of those that did provide secondary information on limitations encountered due to reporting and methodological quality, the majority indicated that the quality was suboptimal. It is possible that systematic review authors may have encountered difficulties in summarising the evidence due to reporting and methodological limitations but chose not to report them. This means that we may have underestimated the reporting and methodological limitations of mediation studies. Because the purpose of this study was to determine the need for a reporting guideline, we conducted an overview of systematic reviews rather than a review of primary reports. The next step is to identify potentially important reporting items through a review of methodological papers and primary research reports.

4.4 Conclusion

Our overview of systematic reviews has shown that the reporting quality and methodological conduct of mediation studies in healthcare is suboptimal. Future work should aim to implement existing methodological guidance, and to develop a reporting

Cashin et al. (2018)
guideline to improve the completeness and transparency of mediation studies in health and medical research.

What is new

Key findings

• Mediation analysis is a popular method for studying the mechanisms by which health interventions or exposures exert their effects.

• This overview shows that over the past decade, there were 54 published systematic reviews including 2008 primary mediation studies, across 11 healthcare fields and 26 health conditions.

• Eighteen of fifty-four (33%) systematic reviews identified limitations in reporting quality and twenty-nine of fifty-four (54%) systematic reviews stated limitations in the methodological conduct of the primary mediation studies.

What this adds to what is known?

• Historically, mediation studies were common in fields such as psychology. This overview has shown that mediation studies are also conducted in health and medical fields across a range of health conditions.

• Systematic reviews of mediation studies have identified suboptimal reporting quality and methodological conduct of primary studies that study the mechanisms of health interventions and exposures.

What is the implication and what should change now?

There is a need to improve the reporting and methodological quality of studies investigating mechanisms. Improving reporting and methodological standards for mediation studies will enhance the ability to evaluate, reproduce and synthesise the findings of mediation studies. It may also minimise reporting bias in systematic reviews of mediation studies.
Authors’ contributions

AC, HP and JM conceptualised and designed the study. SL, SH, CW, SK and NH provided guidance and overviewed the project. AC, HP screened and selected articles. AC, HP and GM extracted data. AC analysed data. AC and HP wrote the first draft of the manuscript. SL, SH, GM, CW, SK, NH and JM provided feedback on the manuscript. All authors approved the final version of the manuscript.
